

# Principle of secondary cycle of solar power generation

## Overview

---

In the thermodynamic solar power process, electric power obtained by using solar energy to heat the fluid (HTF) water, air, or carbon dioxide, which then transformed into a gas (steam for water), which moves the turbines analogously to the traditional thermo-electric. In the thermodynamic solar power process, electric power obtained by using solar energy to heat the fluid (HTF) water, air, or carbon dioxide, which then transformed into a gas (steam for water), which moves the turbines analogously to the traditional thermo-electric. Power cycles are used in all thermal energy plants—including coal, natural gas, and nuclear energy plants—to convert heat into electricity. Concentrating solar-thermal power (CSP) plants are no different, but use sunlight to generate the heat to power a turbine. So the energy generation from solar radiation can be in the form of electrical energy or thermal Energy. Solar panels, also called PV panels, are combined. An improvement of supercritical carbon dioxide Brayton cycle with regeneration coupled with a (carbon dioxide/ethane) shielded as a second cycle before starting the cooling phase in a solar tower installation was carried out. Thermal energy storage (TES) is a technology that stocks thermal energy by heating or cooling a storage medium so that the stored. Solar thermal-electric power systems collect and concentrate sunlight to produce the high temperatures needed to generate electricity.
