## Overview

---

Solar cell When sunlight strikes a solar cell, an electron is freed by the photoelectric effect. The two dissimilar semiconductors possess a natural difference in electric potential (voltage), which causes the electrons to flow through the external circuit, supplying power to the load. Evidence of the first known tools used to concentrate the Sun's rays onto kindling to make fire include Yangsui burning. That energy streams through space in the form of electromagnetic radiation—light, in all its visible and invisible wavelengths. Earth receives only a tiny fraction of this radiant power, but it is still vastly more than all of humanity's energy consumption. The research has been underway since very beginning for the development of an affordable, in-exhaust utilized for the global sustainable electric power generation. But how exactly does sunlight get transformed into electricity that powers our homes, businesses, and gadgets?

Understanding the science behind solar energy.
